Linear mixed models capture multiple "levels" of variation in data. They were introduced by R. A. Fisher in 1918 to study genetic and non-genetic components of variance in quantitative traits.

This talk will describe some applications of random matrix theory to understand spectral behavior and principal components analysis for classical covariance estimates in these models.

Measure *p* quantitative traits in n/2 pairs of twins. For i = 1, ..., n/2, model this with two "levels" of variation as

$$Y_{i,1} = \alpha_i + \varepsilon_{i,1} \in \mathbb{R}^p$$
$$Y_{i,2} = \alpha_i + \varepsilon_{i,2} \in \mathbb{R}^p$$

▲□▶▲□▶▲壹▶▲壹▶ 壹 ∽۹ペペ 5/37

Measure *p* quantitative traits in n/2 pairs of twins. For i = 1, ..., n/2, model this with two "levels" of variation as

$$Y_{i,1} = \alpha_i + \varepsilon_{i,1} \in \mathbb{R}^p$$
$$Y_{i,2} = \alpha_i + \varepsilon_{i,2} \in \mathbb{R}^p$$

Here, $\alpha_i \in \mathbb{R}^p$ is the shared genetic effect in the *i*th twin pair, and $\varepsilon_{i,1}, \varepsilon_{i,2} \in \mathbb{R}^p$ are individual variations.

Measure p quantitative traits in n/2 pairs of twins. For i = 1, ..., n/2, model this with two "levels" of variation as

$$Y_{i,1} = \alpha_i + \varepsilon_{i,1} \in \mathbb{R}^p$$

$$Y_{i,2} = \alpha_i + \varepsilon_{i,2} \in \mathbb{R}^p$$

Here, $\alpha_i \in \mathbb{R}^p$ is the shared genetic effect in the *i*th twin pair, and $\varepsilon_{i,1}, \varepsilon_{i,2} \in \mathbb{R}^p$ are individual variations.

Assume these are random and independent,

$$\alpha_i \stackrel{iid}{\sim} \mathcal{N}(\mathbf{0}, \boldsymbol{\Sigma}_{\mathcal{A}}), \qquad \varepsilon_{i,j} \stackrel{iid}{\sim} \mathcal{N}(\mathbf{0}, \boldsymbol{\Sigma}_{\mathcal{E}})$$

Measure p quantitative traits in n/2 pairs of twins. For i = 1, ..., n/2, model this with two "levels" of variation as

$$Y_{i,1} = \alpha_i + \varepsilon_{i,1} \in \mathbb{R}^p$$

$$Y_{i,2} = \alpha_i + \varepsilon_{i,2} \in \mathbb{R}^p$$

Here, $\alpha_i \in \mathbb{R}^p$ is the shared genetic effect in the i^{th} twin pair, and $\varepsilon_{i,1}, \varepsilon_{i,2} \in \mathbb{R}^p$ are individual variations.

Assume these are random and independent,

$$\alpha_i \stackrel{iid}{\sim} \mathcal{N}(\mathbf{0}, \boldsymbol{\Sigma}_{A}), \qquad \varepsilon_{i,j} \stackrel{iid}{\sim} \mathcal{N}(\mathbf{0}, \boldsymbol{\Sigma}_{E})$$

Only the $Y_{i,j}$'s (not the α_i 's or $\varepsilon_{i,j}$'s) are observed. From this, we wish to separately understand Σ_A and Σ_E .

Example: Mutations in fruit flies [McGuigan et al '14]

In inbred lines of fruit lines, how much phenotypic variation arises due to genetic mutations across the generations?

Example: Mutations in fruit flies [McGuigan et al '14]

In inbred lines of fruit lines, how much phenotypic variation arises due to genetic mutations across the generations?

Model traits (gene expression measurements) in the j^{th} offspring of the i^{th} inbred line as

$$Y_{i,j} = \alpha_i + \varepsilon_{i,j}.$$

The covariance Σ_A of α_i 's is the mutational variation of interest.

- genotypes $\{0,1,2\}$ at m SNPs, $X \in \mathbb{R}^{n imes m}$

Fisher's infinitesimal model:

$$Y = XA + E$$

• $A \in \mathbb{R}^{m \times p}$ has independent rows $\alpha_1, \ldots, \alpha_m$. Each $\alpha_i \in \mathbb{R}^p$ is the contribution of the *i*th SNP to the observed traits.

In *n* individuals, measure:

- *p* quantitative traits, $Y \in \mathbb{R}^{n \times p}$
- genotypes $\{0,1,2\}$ at m SNPs, $X \in \mathbb{R}^{n imes m}$

Fisher's infinitesimal model:

$$Y = XA + E$$

- A ∈ ℝ^{m×p} has independent rows α₁,..., α_m. Each α_i ∈ ℝ^p is the contribution of the ith SNP to the observed traits.
- $E \in \mathbb{R}^{n \times p}$ has independent rows $\varepsilon_1, \ldots, \varepsilon_n$. Each $\varepsilon_j \in \mathbb{R}^p$ is the residual trait variation in the j^{th} individual.

In *n* individuals, measure:

- p quantitative traits, $Y \in \mathbb{R}^{n \times p}$
- genotypes $\{0,1,2\}$ at m SNPs, $X \in \mathbb{R}^{n imes m}$

Fisher's infinitesimal model:

$$Y = XA + E$$

- A ∈ ℝ^{m×p} has independent rows α₁,..., α_m. Each α_i ∈ ℝ^p is the contribution of the ith SNP to the observed traits.
- $E \in \mathbb{R}^{n \times p}$ has independent rows $\varepsilon_1, \ldots, \varepsilon_n$. Each $\varepsilon_j \in \mathbb{R}^p$ is the residual trait variation in the j^{th} individual.

The covariance Σ_A of α_i 's is the (additive) genetic covariance. The relative size of Σ_A to Σ_E provides a measure of heritability.

A general model with k levels of variation is

$$Y = U_1 A_1 + \ldots + U_k A_k \in \mathbb{R}^{n \times p}$$

A general model with k levels of variation is

$$Y = U_1 A_1 + \ldots + U_k A_k \in \mathbb{R}^{n \times p}$$

A₁,..., A_k are random and unobserved, with n₁,..., n_k independent rows distributed as N(0, Σ₁),..., N(0, Σ_k).

This is the random matrix model that I'll discuss.

- What is the bulk eigenvalue distribution for large n, n₁, ..., n_k, p?
- 2. What is the behavior of principal components in spiked settings?

Aside: The case of isotropic noise

A simple statistical null hypothesis in this model is

$$\Sigma_r = \sigma_r^2 \operatorname{Id}$$

for every $r \in \{1, ..., k\}$, i.e. the distribution of every random effect is isotropic noise.

< □ ▶ < □ ▶ < ≧ ▶ < ≧ ▶ E の Q @ 11/37

Aside: The case of isotropic noise

A simple statistical null hypothesis in this model is

$$\Sigma_r = \sigma_r^2 \operatorname{Id}$$

for every $r \in \{1, ..., k\}$, i.e. the distribution of every random effect is isotropic noise.

This setting is special: We may write $\widehat{\Sigma} = G^{\mathsf{T}} F G$ where

$$G = \begin{pmatrix} G_1 \\ \vdots \\ G_k \end{pmatrix}, \quad F = (\sigma_r F_{rs} \sigma_s)_{r,s=1}^k.$$

This setting is special: We may write $\widehat{\Sigma} = G^{\mathsf{T}} F G$ where

$$G = \begin{pmatrix} G_1 \\ \vdots \\ G_k \end{pmatrix}, \quad F = (\sigma_r F_{rs} \sigma_s)_{r,s=1}^k.$$

Here, $\widehat{\Sigma}$ is related to the sample covariance model. We've obtained more refined results in this setting than in the general case, due a known local law [Knowles, Yin '17].

Our computations in the approximating free model use relations between (conditional) Cauchy and \mathcal{R} -transforms:

Let $\kappa_\ell(a_1,\ldots,a_\ell)$ be the ℓ^{th} order non-crossing cumulant, and

$$egin{aligned} G_{a}(z) &= au((z-a)^{-1}) = \sum_{\ell=0}^{\infty} z^{-(\ell+1)} au(a^{\ell}), \ \mathcal{R}_{a}(z) &= \sum_{\ell=1}^{\infty} z^{\ell-1} \kappa_{\ell}(a,\ldots,a). \end{aligned}$$

The moment-cumulant relations for non-crossing partitions give

$$G_a(z) = (z - \mathcal{R}_a(G_a(z)))^{-1}.$$

In addition to approximating $n^{-1} \operatorname{Tr} R(z)$, we also need

 n^{-1} Tr AR(z)

<□ ▶ < □ ▶ < ■ ▶ < ■ ▶ < ■ ▶ ■ のへで 34/37

for certain (random) matrices A.

In addition to approximating $n^{-1} \operatorname{Tr} R(z)$, we also need

 n^{-1} Tr AR(z)

for certain (random) matrices A. We introduce augmented transforms and some associated moment-cumulant relations:

$$G_{a,w}(z) = \tau(a(z-w)^{-1}) = \sum_{\ell=0}^{\infty} z^{-(\ell+1)} \tau(aw^{\ell})$$

 $\mathcal{R}_{a,w}(z) = \sum_{\ell=1}^{\infty} z^{\ell-1} \kappa_{\ell}(a, w, \dots, w).$

Lemma (Fan, Sun, Wang '19)

$$G_{a,w}(z) = \mathcal{R}_{a,w}(G_w(z))G_w(z)$$

In the setting $\Sigma_r \neq \sigma_r^2 \, \text{Id}$, we use a strong asymptotic freeness result to show that eigenvalues stick to $\text{supp}(\mu_0)$:

In the setting $\Sigma_r \neq \sigma_r^2 \, \text{Id}$, we use a strong asymptotic freeness result to show that eigenvalues stick to $\text{supp}(\mu_0)$:

Theorem (Fan, Sun, Wang '19)

Let W_1, \ldots, W_p be independent GOE, H_1, \ldots, H_q deterministic with bounded norm, and w_1, \ldots, w_p free semicircular elements. For any fixed self-adjoint *-polynomial Q and $\delta > 0$, a.s. for large n,

 $\operatorname{spec}(Q(\{W_i\}_{i=1}^p, \{H_j\}_{j=1}^q)) \subset \operatorname{spec}(Q(\{w_i\}_{i=1}^p, \{H_j\}_{j=1}^q))_{\delta}.$

The GUE analogue was proven in [Male '12], and extended to complex Wigner matrices in [Belinschi, Capitaine '17].

In the setting $\Sigma_r \neq \sigma_r^2 \, \text{Id}$, we use a strong asymptotic freeness result to show that eigenvalues stick to $\text{supp}(\mu_0)$:

Theorem (Fan, Sun, Wang '19)

Let W_1, \ldots, W_p be independent GOE, H_1, \ldots, H_q deterministic with bounded norm, and w_1, \ldots, w_p free semicircular elements. For any fixed self-adjoint *-polynomial Q and $\delta > 0$, a.s. for large n,

 $\operatorname{spec}(Q(\{W_i\}_{i=1}^p, \{H_j\}_{j=1}^q)) \subset \operatorname{spec}(Q(\{w_i\}_{i=1}^p, \{H_j\}_{j=1}^q))_{\delta}.$

The GUE analogue was proven in [Male '12], and extended to complex Wigner matrices in [Belinschi, Capitaine '17].

We follow proof ideas of these works, and of [Schultz '05] in the pure GOE setting.
